Titelbild

Eine der wichtigsten Fragestellungen der Archäometallurgie ist die nach der Herkunft von Metallartefakten und deren Zuordnung zur Erzlagerstätte. Hierzu haben in den letzten Jahren verschiedene Forschungsprojekte im Mittelmeerraum grundlegende Beiträge geliefert. Als sehr nützliche naturwissenschaftliche Untersuchungsmethode hat sich dabei die Analyse von Bleiisotopen erwiesen.

Das Titelbild zeigt einen der bekannten „Ochsenhautbarren“, eine für das 2. Jahrtausend v. Chr. typische Handelsform von Kupfer. Bronzezeitliche Dolche repräsentieren das Endprodukt der Metallurgiekette. Im Diagramm sind die Bereiche der Bleiisotopenzusammensetzung von Erzen aus der Ägäis und von Zypern dargestellt. Da sich die Isotopenverhältnisse des Bleis bei der Kupfergewinnung und Weiterverarbeitung nicht ändern, erlaubt ihre Messung in Zwischen- und Endprodukten Rückschlüsse auf die Ausgangserze.

Place Names

A Guide in Detecting Ancient Gold Mines in Iran

Introduction

The remnants of ancient mining and metallurgy are a very effective guide for discovering ore deposits. Most of the presently known ore deposits, with ore minerals known and used in the old world, are indeed rediscovered following the remnants of ancient mining and metallurgy. This is true especially for the countries with long history and long culture.

Almost all modern copper, gold, silver, lead, iron and many other mineral deposits in the Middle East, Minor Asia, central Asia, northern Africa and south and central Europe are indeed rediscovered following the ancient mining traces. Application of ancient mining remnants in prospection has unfortunately not received any serious attention by economic geologists and has not any scientific discipline or methodology. Beside the economic aspect, a systematic study for determination and classification of ancient mining-metallurgy sites, in time and geography, can contribute much valuable informations in archaeological studies. There is no doubt that it is necessary to try to develop a method for application of ancient mining culture in prospection for new ore deposits. Combination of such a method with modern techniques in prospection will give much better results.

The knowledge about ancient mining and metallurgy and their traces can be grouped into two categories:

1. Physical remains, like ancient mine diggings, kilns and/or slag sites, ruined workshops and workers' settlements, the tools and artifacts etc.
2. Cultural remains, like travellers itineraries, historical, scientific and technical texts, informations by local people, etc.

One of the most informative remains of the second category is the locality names, especially the name of villages.

In the present paper an attempt is performed to apply the proper place names in rediscovering the remote ancient gold mines in Iran. A brief note about the ancient gold, copper, silver and lead mines in Anatolia is also presented.

Place Name Analysis for Gold Prospection in Iran

The geographical and locality names of villages and cities, as well as the names of mountains, rivers, vallies etc., from the whole Iranian territory are reviewed, interpreted and processed. The base topography map of Iran 1:250,000 (JOG) is taken as the reference source for this study. Some 3200 names (out of 100,000) which could probably reflect any mining and metallurgy of any evidence of mineral resources were picked up and processed. The analysis lead the authors to conclude that the names may refer to several different metals and minerals, like gold, copper, iron, silver, lead, gypsum, rock salt and other salts, alum or vitriol, sulfur, gems, pottery clays, petroleum and asphalt, building stones, mineral and/or hot water, etc. The names which may reflect gold were chosen as an example for further study.

From 3200 place names, which could probably reflect ancient mining 312 are considered to relate to gold. A list of these names in Latin alphabet is prepared (Table 34.1). The geographical distribution of names is shown in Fig. 34.1. According to the probability values indicating ancient gold producing sites, the names are grouped into categories A, B, C, D, and E. The probability value of names is assigned on the base of five parameter:

1. Meaning of the name; in all names the words "Zar", "Ghezel" and "Talā", which mean gold, is a component of the name.
2. Geological and metallogenetic setting of the site of name; the country rocks in the site of a name may be proper for occurrence of gold or not. Therefore the rock type of each place is considered on the base of geological map of Iran (1:2,500,000) and symbolized as m, m₁, m₂, m₃, g, Tr, Jk, K, Ki, Kp, T, P, Nv, Ns, and A (Table 34.1). The probability value is higher for the name with more proper geological setting.
3. Presence of known gold occurrences close to the locality.
4. Historical and cultural reputation of the concerned area for gold production in ancient times.

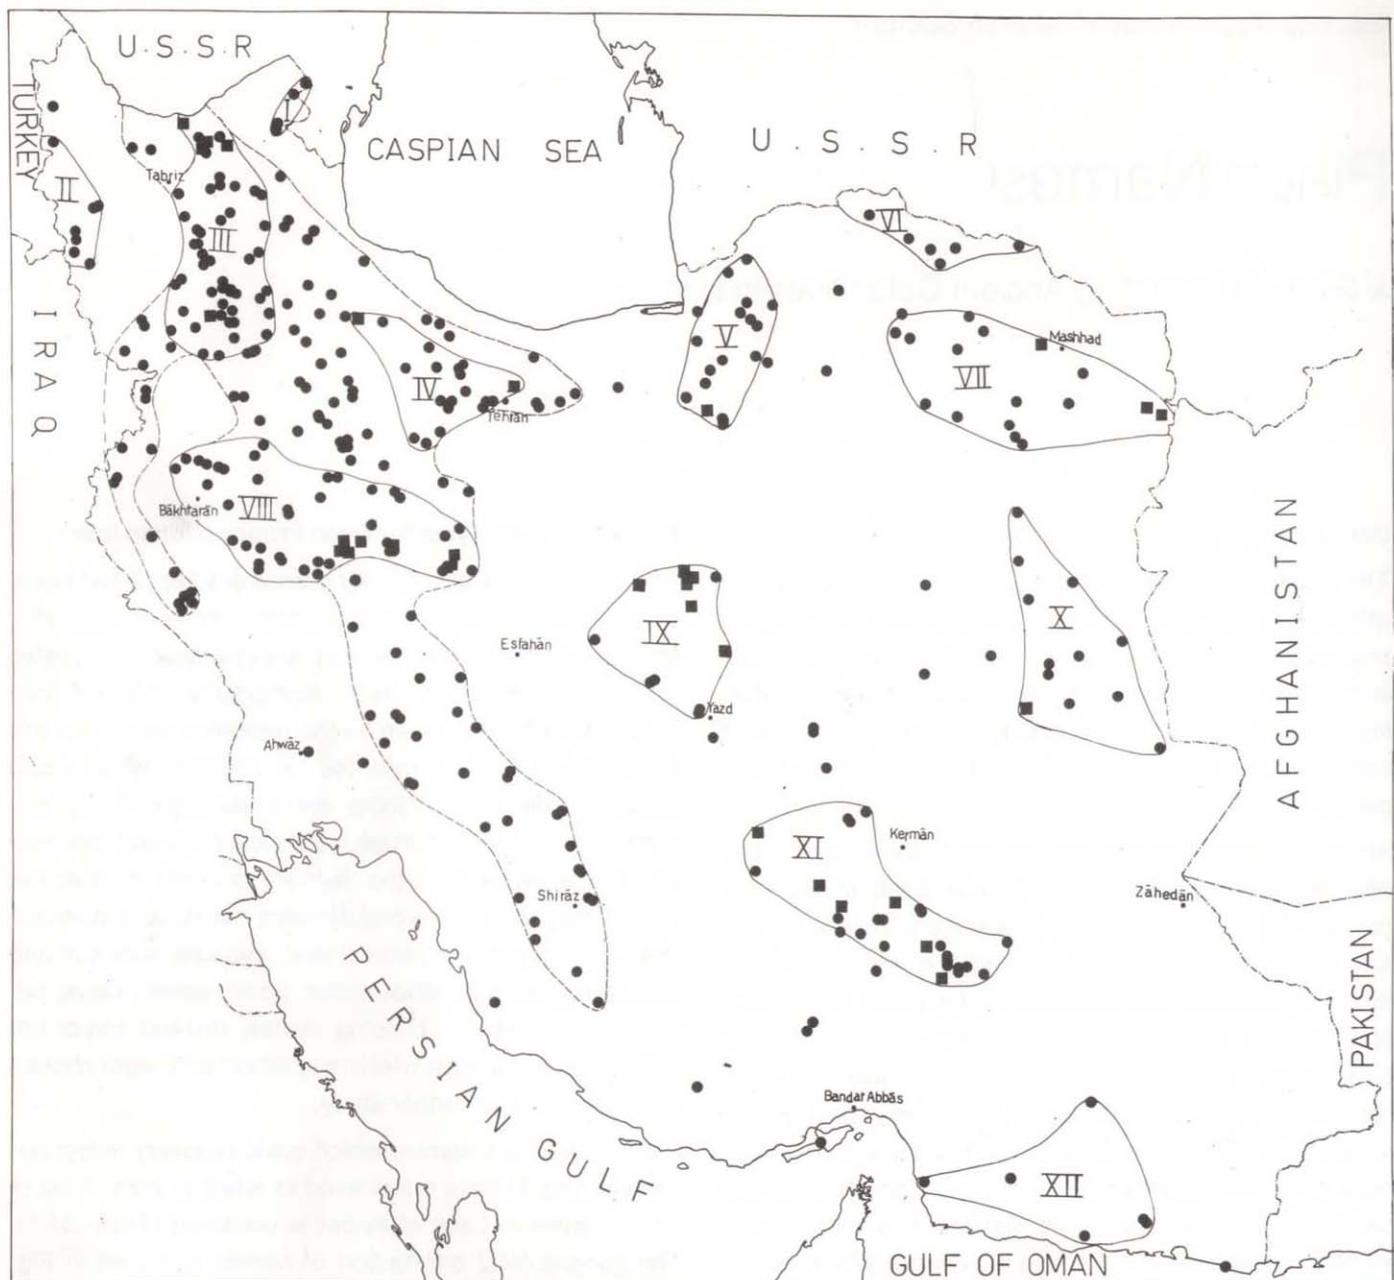

Fig. 34.1: Geographical distribution of place names, which probably reflect ancient mining and/or metallurgy sites for gold in Iran (dots) and the localities of known gold occurrences (squares). Roman numbers I to XII refer to twelve cluster of names, where the probability values of names and their frequency are higher. I = Moghān, II = Orumieh, III = Ahar-Takāb, IV = Zanjan-Tehran, V = Gorgān-Dāmghān, VI = Bojnurd, VII = Mashhad, VIII = Bākhtārān-Delijān, IX = Anārak-Nāiin, X = Birjand, XI = Rafsanjān-Bam, XII = South Jāzmuriān

5. Personal experience and deduction of the authors in interpretation of the name.

Category A includes the names, which the presence of gold in their sites is proved, like "Zarshurān", "Zarrin", "Kuhzar", "Ghalezari" etc. (Nos. 6, 10, 17, 26, 27 in Table 34.2). Categories B, C, D and E include respectively the names, which the presence of gold in their sites is considered as very probable ($B > 20\%$), probable ($C > 10\%$, $D > 5\%$) and faintly possible ($E > 1\%$). The figures in percent are approximate. For example in the case of category B, from five cases at least one is named after ancient gold mining or gold processing.

The sites of names, when plotted on a map of Iran, shows a zonation, which coincides well with the sites of known gold provinces and occurrences. Some 12 clusters of names are recognized, which we refere to as province I to XII (Figs 36.1–5 and Table 34.1):

- I. Moghān Province,
- II. Orumieh Province,
- III. Ahar-Takāb Province,
- IV. Zanjan-Tehran Province,
- V. Gorgān-Dāmghān Province,
- VI. Bojnurd Province,
- VII. Mashhad Province,

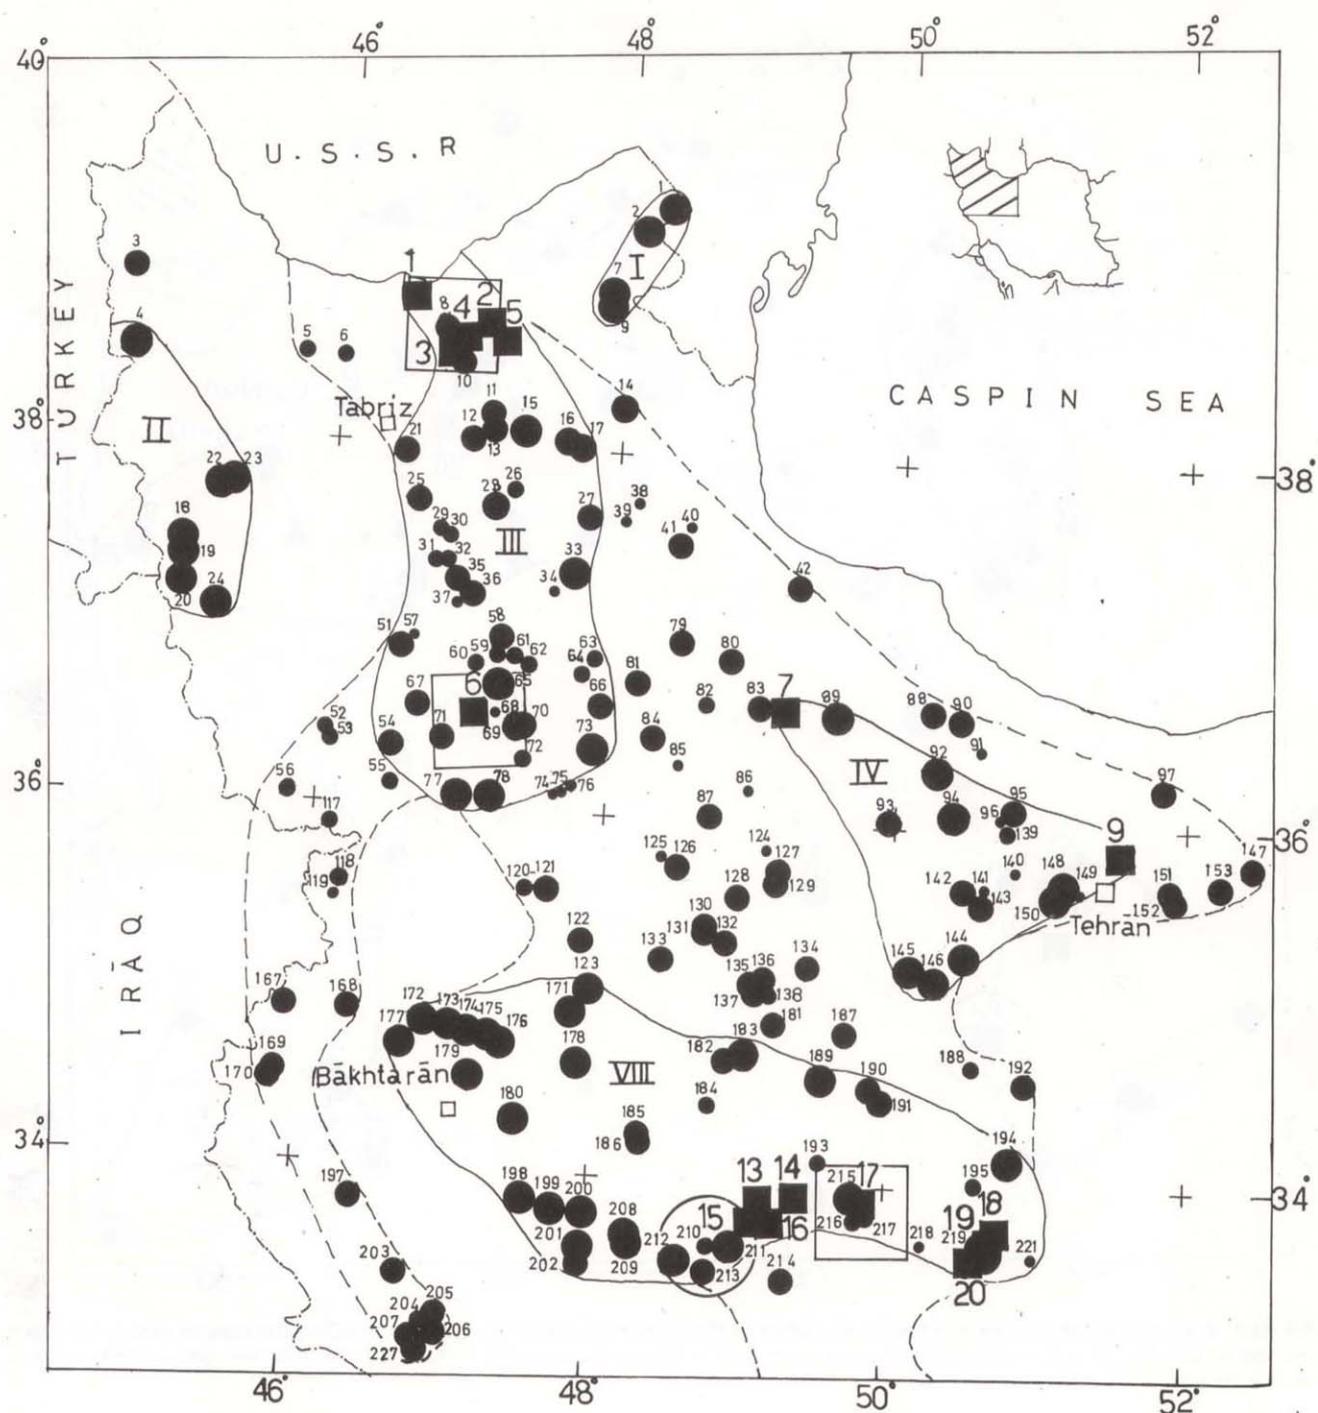

Fig. 34.2: Geographical distribution of place names which probably reflect ancient mining and/or metallurgical sites for gold in NW-Iran (dots): For the names see Table 34.1. The size of the dots represents probability value of each name: largest over 20%, smallest over 1% and the two medium sizes over 10% and 5% respectively. The squares indicate localities of known gold occurrences. Circles and blank squares indicate place names for gold where ancient gold mines are rediscovered in their localities (In the case of the circle the gold occurrence is rediscovered by application of place name analyses method). For the names see Table 34.2. I = Moghān province, II = Orumieh province, III = Ahar-Takāb province, IV = Zanjān-Tehran province, VIII = Bākhtarān-Delijān province

- VIII. Bākhtarān (Kermānshāh)-Delijān Province,
- IX. Anārak-Nāiin Province,
- X. Birjand Province,
- XI. Rafsanjān-Bam Province,
- XII. South Jāzmuriān Province.

The frequency of names along a wide belt, which runs all along west Iran (west Iran Belt) is higher than in the rest of the country. This belt includes Āzarbāyjān, Kordestān, Zanjān, Hamadān, Tehran, some parts of Lorestān, Khuzestān and Fārs states. Some provinces like Moghān,

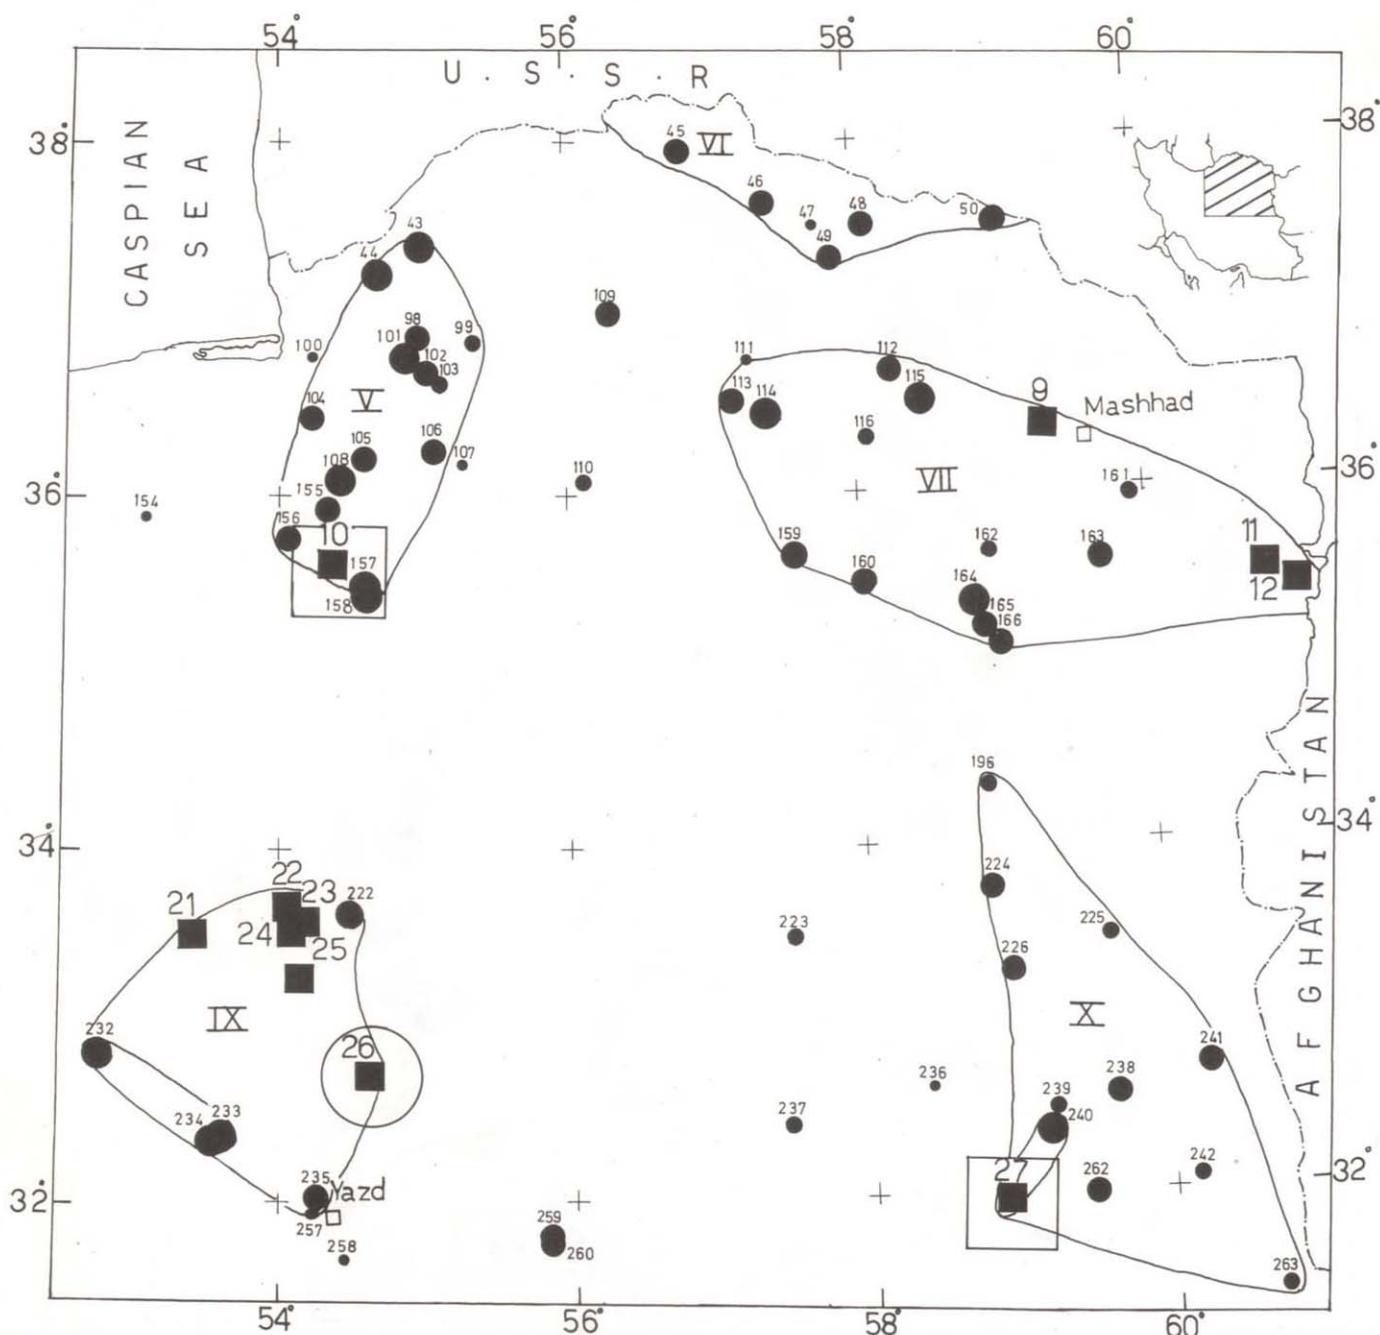

Fig. 34.3: Geographical distribution of place names which probably reflect ancient mining and/or metallurgical sites for gold in NE-Iran. (For legend see Fig. 34.2). V = Gorgān-Dāmghān province, VI = Bojnurd province, VII = Mashhad province, IX = Anārak-Nāīin province, X = Birjand province

Orumieh, and Ahar-Takāb seem to extend to the neighbouring countries. In some of the provinces, like Ahar-Takāb, Bākhtarān (Kermānshāh)-Delijān, Mashhad, presence of gold could be expected by the presence of a few known gold occurrences, via the travellers' itineraries, historical texts etc. But in some provinces like Moghān, Orumieh, Gorgān-Dāmghān and Birjand much little is known. The sites of 32 known gold deposits and occurrences of Iran are plotted on the same map for a comparison with the sites of the place names (Figs 34.1–3 and 5).

A list of these gold occurrences is presented in Table 34.2. In such occurrences gold is present either as main element or as associate with copper, lead and zinc. As mentioned elsewhere in this paper the names of several known gold occurrences reflect clearly gold in their meanings (Nos 6, 10, 17, 26 and 27 in Table 34.2). This fact shows that the place name analysis can be an effective method in prospection for gold. On the other hand, the names of some known gold occurrences and presence of ancient working in all of them show that all known gold occur-

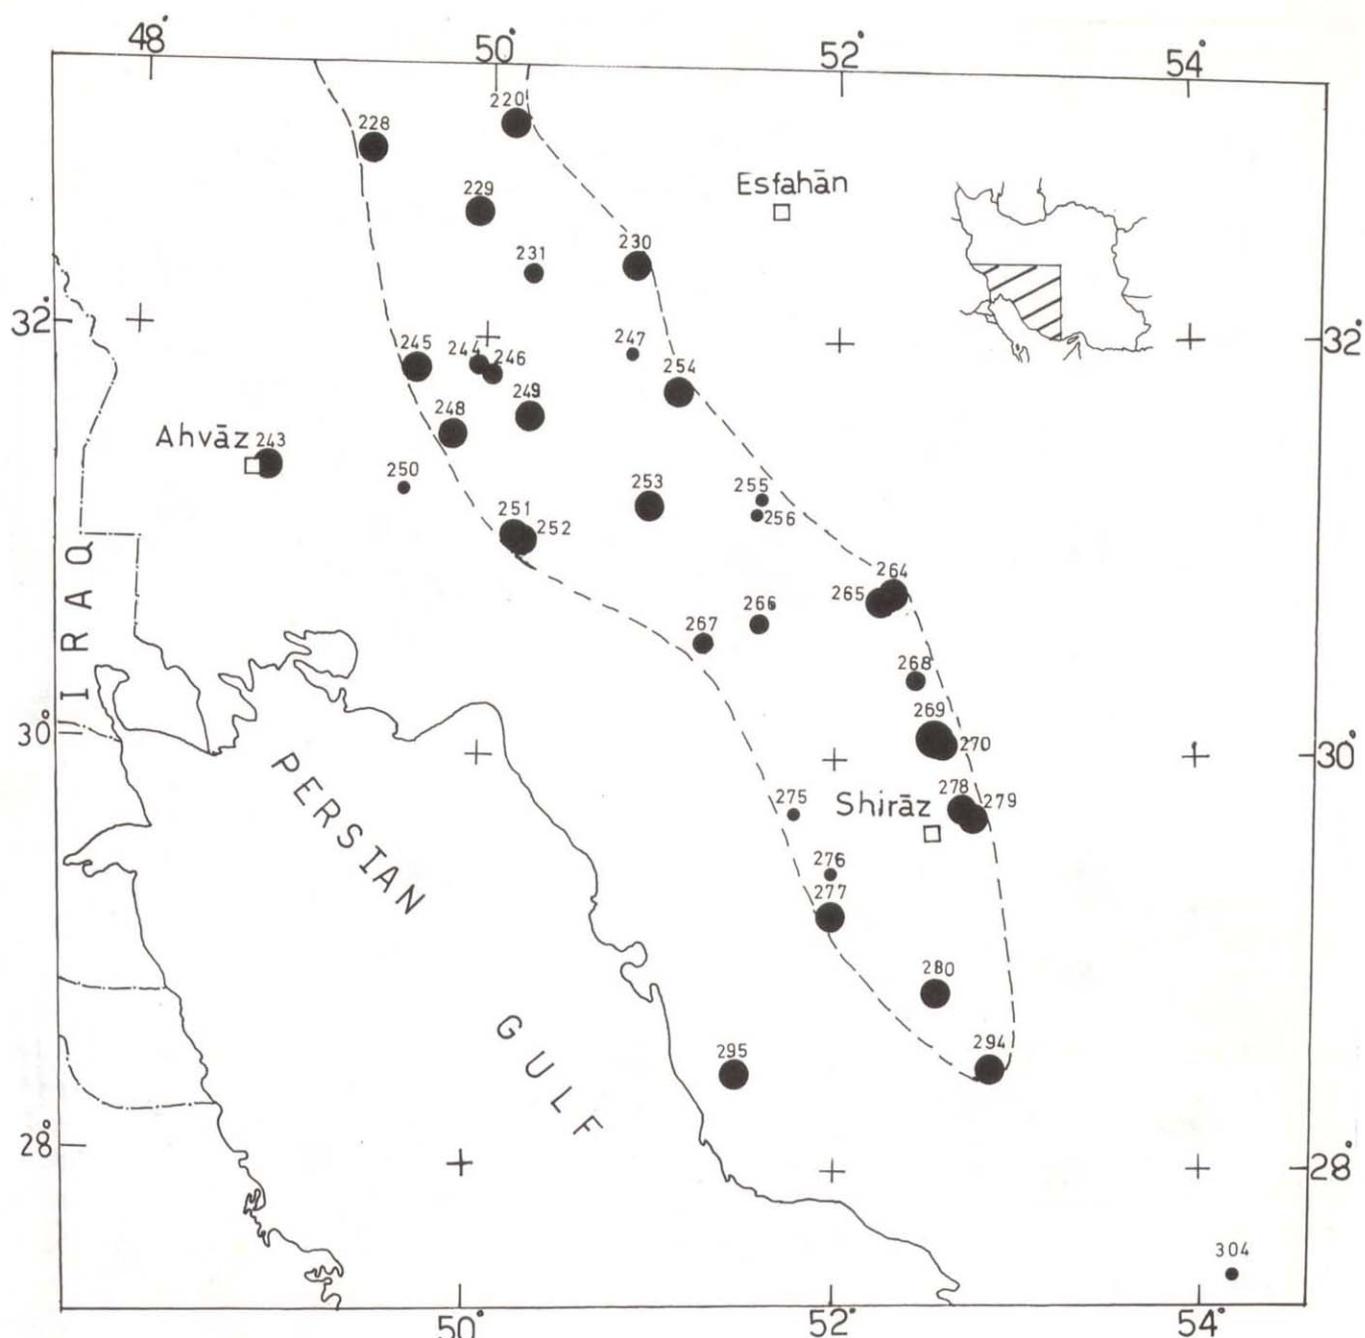

Fig. 34.4: Geographical distribution of place names which probably reflect ancient mining and/or metallurgical sites for gold in SW-Iran
(For legend see Fig. 34.2)

rences of Iran are indeed ancient gold mines which have been rediscovered. Occurrences "Zarrin" and "Zarrin-khāni" (No. 26 in Table 34.2 and No. 210 in Table 34.1) were rediscovered recently by application of the meaning of place names and following the ancient mining remnants. A brief description about each occurrence is as follows:

Zarrin Ancient Gold Mine

Zarrin is the name of a village in central Iran on an ancient karavan road from Yazd to Khorāsān (No. 26 in Table

34.2). It has presently only a few families as inhabitants. The ruins of a mud castle adjacent to the village indicates its previous glory. The castle has been probably the living site of the gold miners. The word "Zarrin" means "golden" or "with gold". This meaning was the motive of one of the present authors and co-workers in 1985 for discovering Zarrin ancient gold mine¹. Exploration work is intermittently performed by the same geologists from the Geological Survey of Iran. Several ancient diggings in different places around the Zarrin village, at the southeast and

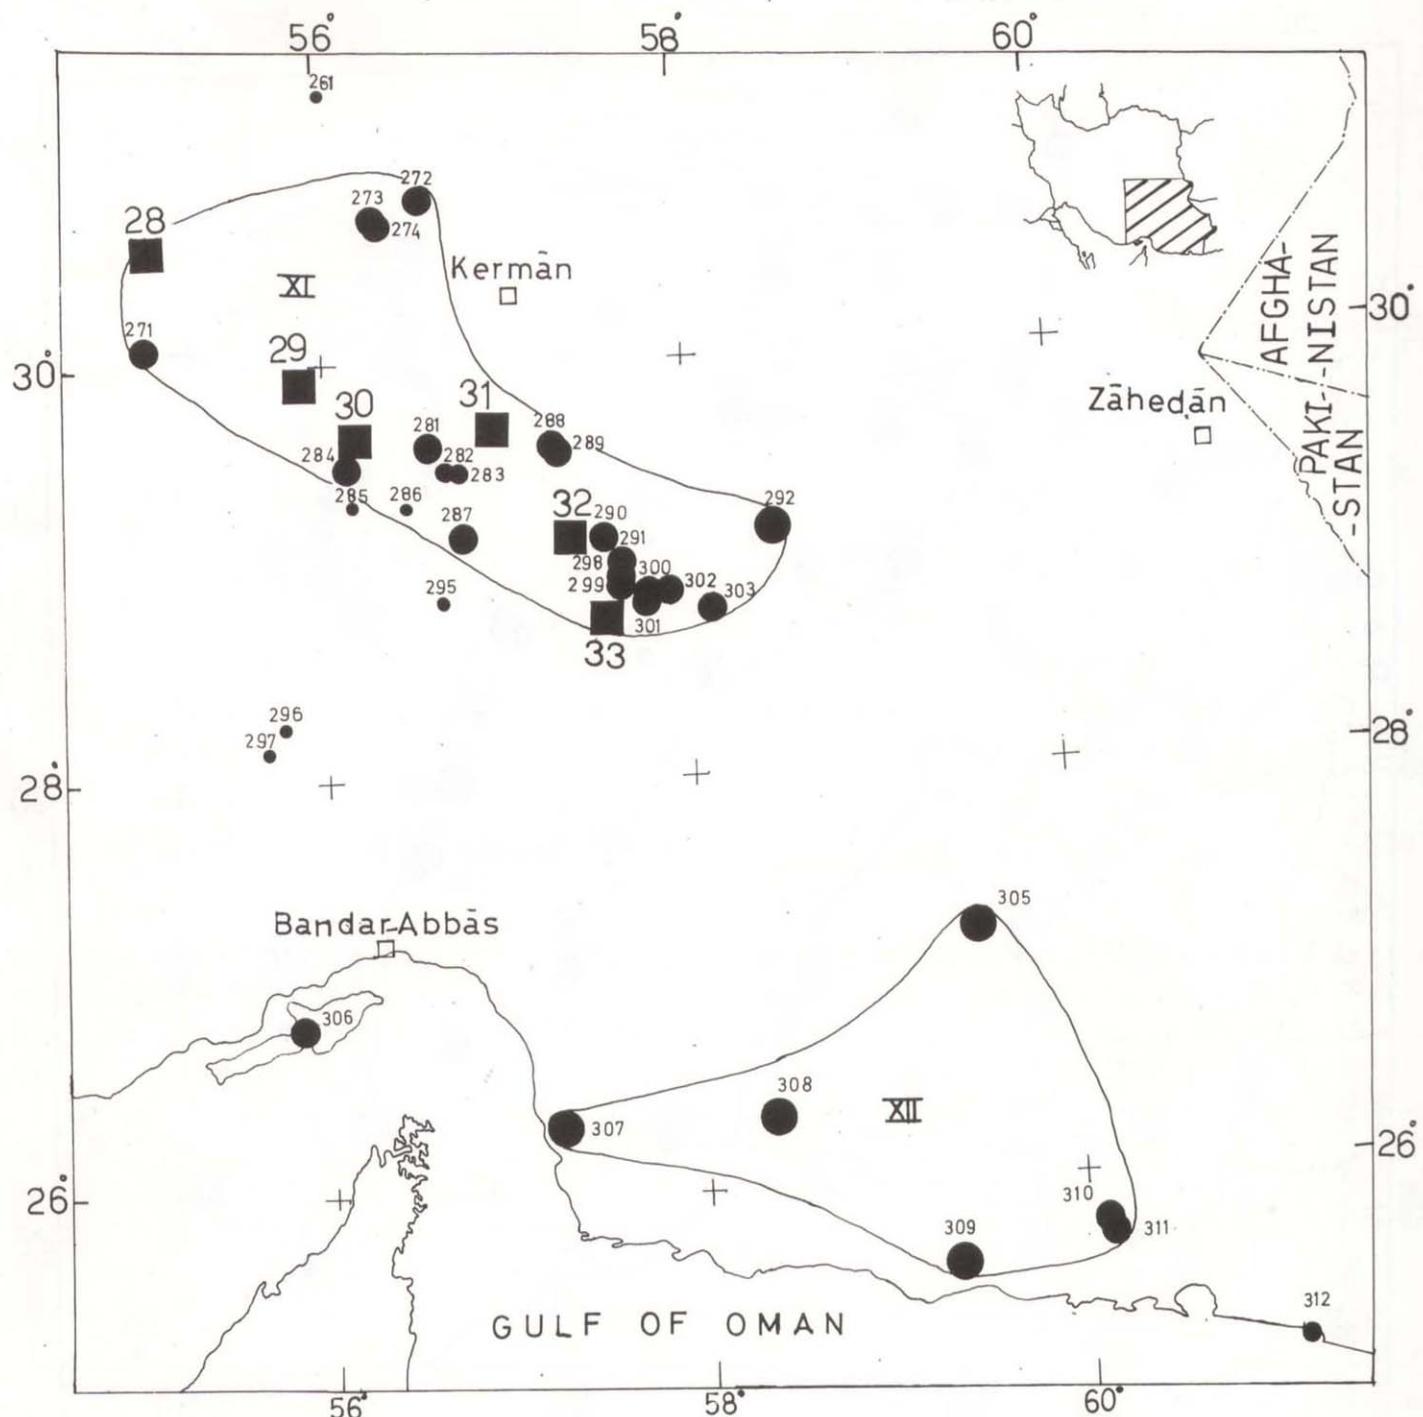

Fig. 34.5: Geographical distribution of place names which probably reflect ancient mining and/or metallurgical sites for gold in SE-Iran
(For legend see Fig. 34.2). XI = Rafsanjān-Bam province, XII = South Jāzmuriān province

southwest foothills of the Zarrin Mountain are found. The diggings are located in alluvial fans of three rivers.

The results of the first stage of washing in the river bed with most frequent old diggings, i.e. "Zarrin-e-Kuchak river" showed about 1 g/ton gold in the river sands. A few big grains of native gold, the biggest being 1.70 g were found by washing, as well as by naked eye in the site of ancient diggings. The gold mineralization is apparently in the crystalline complex of Late Paleozoic-Early Mesozoic, along a contact zone between a granite mass and overlying schists, as well as in the schists.

Zarrinkhāni Gold Indication

Zarrinkhāni is the name of a village 100 km east of Khorramābād, Lorestan, west Iran (No. 210 in Table 34.1). As mentioned above "Zar" is gold and "Khāni" is probably a modified pronunciation of "Kān" which means mine or deposit. Hence "Zarrinkhāni" means probably gold mine. The meaning of this name was the motive for a prospecting team from the Geological Survey of Iran including one of the present authors, to look for gold around Zarrinkhāni². The first field test was carried out by washing 13 samples of sand in the Zarrinkhāni river. In two samples

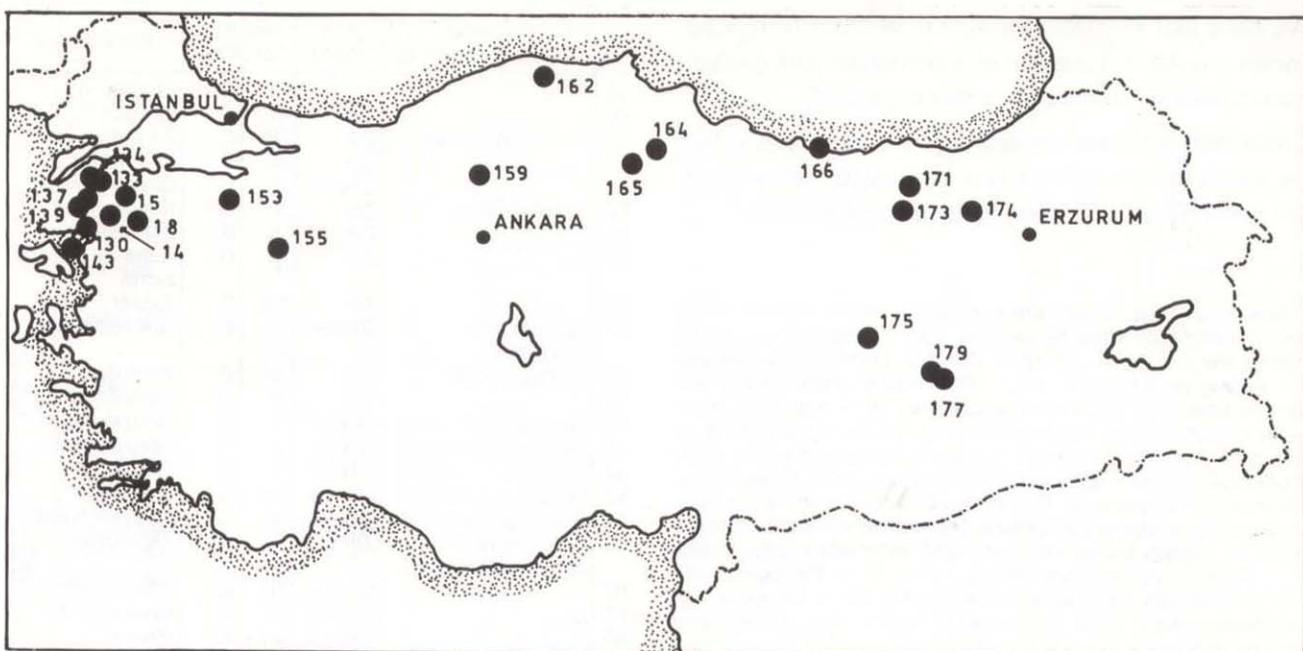

Fig. 34.6: Locality map of some ancient mining and metallurgy sites of Turkey. The names of sites reflect somehow ancient mining and/or metallurgy activities, cf. Table 34.3

gold grains were found. Gold is supposed to be driven from the Upper Cretaceous-Early Tertiary volcanosedimentary rocks, composed of tuff, shales, marls and microconglomerates. This rock sequence is stratigraphically an equivalent of the Upper Cretaceous-Paleogene well known ophiolitic complex along the Zagros thrust zone. More exploration works is required to find out the source rocks.

A brief note about the place names, related to ancient mines in Anatolia:

Some of the ancient mines and metallurgy sites of Anatolia are recently well studied in the frame of a German-Turkish archaeometallurgical project. Round 200 sites with ancient workings are studied and the results are published³. On the base of informations obtained from this two reports a preliminary review of locality names is performed by the present authors.

The ancient mines and/or slag localities are coded as TG 1 to TG 185. In some of the localities several ancient workings, each with its own local name, are clustered under one code (for example: TG 18 and TG 18 D, E, F).

From nearly 200 names of investigated localities 22 names, which reflect clearly or give sign to ancient mining and/or metallurgical activities, are picked up by the present authors (Table 34.3 and Fig. 34.6). From 22 names 15 indicate directly the metals, which have been obtained from the corresponding sites; namely gold, silver, copper and lead (Nos TG 14, 15, 18, 130, 133, 137, 139, 155,

159, 162, 165, 171, 173[?], and 177). In other cases the names indicate mining and/or metallurgy activities without referring to the type of obtained metal. In ten cases the investigations by the German-Turkish team confirm that the metal, which is reflected in the corresponding name, has been the product of that ancient mine (Nos TG 14, 18, 133, 155, 159, 162, 164, 165, 173[?], and 177). In six cases the names clearly indicate gained metal whereas the investigations by German-Turkish team do not mention it (silver in TG 14, 15 and 171, gold in TG 130, copper in TG 137 and lead in TG 139).

Conclusions

The place names can contribute much to rediscover ancient mines and metallurgy sites. This is true especially for those parts of the world with longer culture and history. The systematic and statistical analysis of place names can be applied as an effective method in prospecting for ore deposits. A combination of this method with the ordinary strategic exploration methods will bring about much better results and will reduce the costs. It is equally important from the archaeological point of view. An ancient mining and metallurgy locality is not only a probable ore deposit but it is meanwhile a valuable archaeological site, which may play a key role in some important problems in archaeology. This method is quite effective for discovering such sites.

We hope that the systematic study of place names becomes popular and suggest an international joint geological-archaeological research project to be held.

Concerning the place names for gold prospection in Iran we expect that the informations and results, presented in this paper will be a fair platform for gold prospection.

Table 34.1: Place names which probably reflect ancient mining and metallurgical sites for gold in Iran. Probability values for names are: B > 20%, C > 10%, D > 5%, and E > 1%. Geological setting of places is: m = Pre-Tertiary metamorphic volcano-sedimentary complex; m_1 = Complex 'm' + granitoids; m_2 = Mafic and ultramafics, in association with 'm'; m_3 = complex 'm' of acidic composition; g = Shaly, marly and carbonatic rocks, partly volcanogenetic; M = Mesozoic; Tr = Triassic; JK = Jurassic-Cretaceous; K = Cretaceous; Ki = Lower Cretaceous shales and carbonates; Kp = Upper Cretaceous-Paleogene volcanosedimentary rocks i.e., flysch facies with mafic and ultramafic interbeddings; T = Tertiary volcanosedimentary rocks; P = Paleogene volcanosedimentary (and subvolcanic) rocks; Nv = Neogene volcanosedimentary (and subvolcanic) rocks; Ns = Neogene sedimentary rocks; A = Quaternary

Table 34.2: Some gold and gold bearing copper and polymetallic occurrences in Iran

Locality Index	Place Name	Probable Meaning of Place Name	Seeliger et al. 1984 Pernicke et al. 1985	Interpr. After Name	Locality-(Province)
TG 14	Simirlikursun	Silver bearing Lead	Pb, Zn (Cu, As)	Pb, Ag	Near Karaaydin (Balikesir)
TG 15	Gümüsler	Silver(s)	Pb, Zn, Cu	Ag	A village (Çanakkale)
TG 18	Kızıl Tepe	Gold Hill	Pb, Ag, Au (As)	Au	A hill, Balya (Balikesir)
TG 130	Kızılıkçeli	Gold Keceli?	Fe, As, W, Py	Au	A village near Güre Village (Balikesir)
TG 133	Bakırlik	Copper-lik	Cu, Pb, Zn	Cu	An occurrence near Doğançilar village (Çanakkale)
TG 134	Madaniçi	Mine workings	Pb, Zn, Cu	—	A valley around Koçayayla village (Çanakkale)
TG 137	Hacibekirler	Haci coppers	Pb, Py	Cu	A village (Çanakkale)
TG 139	Kursunu	Lead work	—	Pb	A village (Çanakkale)
TG 143	Maden Adası	Mine Adası	Pb, Zn, Cu, Fe	—	An Island (Balikesir)
TG 153	Maden beleni Tepe	Mine beleni Hill	Pb, Zn (Cu, As)	—	A hill (Bursa)
TG 155	Gümüşkoy	Silver köy	Pb, Ag, Zn (Cu, As, Sb)	Ag	A village (Kütahya)
TG 159	Küçük Bakır Tepe	Small copper Hill	Pb, Ag, Zn	Cu	Işık Dag Pb, Ag, Zn Occurrence (Ankara)
TG 162	Küre or Küre-i-Nihas	Furnace or Furnace of copper (Arabic)	Cu, Zn (Pb, Ag)	Cu	A big copper deposit (Kastamonu)
TG 164	Bakır Çay Madenköy	Copper river Mine koy	Cu, Fe (Pb)	Cu	Derealan/Bakır Çay Copper occurrence (Amasya)
TG 165	Gümüs (Gümüşacıköy)	Silver (Silver acıköy) Küs	Pb, Ag	Ag	A village (Amasya)
	Kus Magarasi Tepe	cavern Hill			
TG 166	Madenköy Mağara	Mine Köy Cavern	Pb, Ag (Zn, Cu, Sb) Pb, Ag (Zn, Cu, Sb)	—	Piraziz-Madenköy (Ordu)
TG 171	Gümüşhane	Silver center	Pb, Zn, Cu	Ag	An ancient mining locality (Gümüşhane)
TG 173	Hazine Mağara	Store cavern	Pb, Zn, Cu, Ag	—	An ancient mining locality
	Zankar	Copper green (Cu Carbonate pigment, malachite?)	Pb, Zn, Cu, Ag	Cu	(Gümüşhane)
TG 174	Maden (near Helva Maden Mine)	Mine	Cu	—	A village near Helva Maden occurrence (Gümüşhane)
TG 175	Mistik Mağara	Mistik cavern	Pb, Ag (Au, Cu)	—	A sector of Keban Polymetallic deposit (Elazig)
TG 177	Kisabekir	Kisa copper	Cu (Zn)	Cu	An occurrence and a village near Ergani deposit (Elazig)
TG 179	Eski Mağara	Eski cavern	Cu	—	A locality near Haçan village (Elazig)

Table 34.3: Place names of some ancient mine and metallurgy sites of Turkey. The name of sites reflect somehow ancient mining and metallurgy activities
